2 balanceplot

# Description

This function plots the balance statistics before and after matching.

# Usage

```
balanceplot(rawdata, matched, pscore.fit,
  longcovnames = NULL,
  main = "Standardized Difference in Means",
  cex.main = 1, cex.vars = 0.8, cex.pts = 0.8,
  mar = c(0, 15, 4, 2), mgp = c(2, 0.25, 0),
  oma = c(0, 0, 0, 0), tcl = -0.2, ...)
```

## **Arguments**

rawdata	unmatched rawdata
matched	matched data using "matching" function
pscore.fit	glm.fit object to get pscore
longcovnames	long covariate names. If not provided, plot will use covariate variable name by default
main	title of the plot
cex.main	font size of main title
cex.vars	font size of variabel names
cex.pts	point size of the estimates
mar	margin of the plot, see ?par for details
mgp	axis margin of the plot, see ?par for details
oma	outer margin of the plot, see ?par for details
tcl	length of ticks, see ?par for details
	other plot options may be passed to this function

#### **Details**

This function plots the balance statistics before and after matching. The open circle dots represent the unmatched balance statistics. The solid dots represent the matched balance statistics. The closer the value of the estimates to the zero, the better the treated and control groups are balanced after matching.

#### **Examples**

bayesglm

Bayesian generalized linear models.

#### **Description**

Bayesian functions for generalized linear modeling with independent normal, t, or Cauchy prior distribution for the coefficients.

## Usage

```
bayesglm (formula, family = gaussian, data,
    weights, subset, na.action,
    start = NULL, etastart, mustart,
    offset, control = glm.control(...),
    model = TRUE, method = "glm.fit",
    x = FALSE, y = TRUE, contrasts = NULL,
    prior.mean = 0, prior.scale = 2.5,
    prior.scale.for.intercept = 10, prior.df = 1,
    scaled = TRUE, n.iter = 100, ...)

bayesglm.fit (x, y, weights = rep(1, nobs),
    start = NULL, etastart = NULL,
    mustart = NULL, offset = rep(0, nobs), family = gaussian(),
    control = glm.control(), intercept = TRUE,
    prior.mean=0, prior.scale=2.5, prior.scale.for.intercept=10,
    prior.df=1, scaled=TRUE)
```

#### **Arguments**

formula a symbolic description of the model to be fit. The details of model specification are given below.

family a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)

4 bayesglm

data an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment (formula), typically the environment from which glm is called. weights an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. an optional vector specifying a subset of observations to be used in the fitting subset process. a function which indicates what should happen when the data contain NAs. The na.action default is set by the na.action setting of options, and is na.fail if that is unset. The "factory-fresh" default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful. starting values for the parameters in the linear predictor. start starting values for the linear predictor. et.ast.art. starting values for the vector of means. mustart offset this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length either one or equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if both are specified their sum is used. See model.offset. a list of parameters for controlling the fitting process. See the documentation for control glm.control for details. a logical value indicating whether model frame should be included as a compomodel nent of the returned value. the method to be used in fitting the model. The default method "glm.fit" method uses iteratively reweighted least squares (IWLS). The only current alternative is "model.frame" which returns the model frame and does no fitting. х, у For glm: logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value. For glm. fit: x is a design matrix of dimension n \* p, and y is a vector of observations of length n. an optional list. See the contrasts.arg of model.matrix.default. contrasts intercept logical. Should an intercept be included in the *null* model? prior mean for the coefficients:default is 0. Can be a vector of length equal to prior.mean the number of predictors (including the intercept, if any). If it is a scalar, it is expanded to the length of this vector. prior scale for the coefficients: default is 2.5. Can be a vector of length equal to prior.scale the number of predictors (including the intercept, if any). If it is a scalar, it is expanded to the length of this vector. prior.scale.for.intercept prior scale for the intercept: default is 10. for t distribution: default is 1 (Cauchy). Set to Inf to get normal prior distribuprior.df tions. Can be a vector of length equal to the number of predictors (including the intercept, if any). If it is a scalar, it is expanded to the length of this vector. if scaled = TRUE, then the prior distribution is rescaled: default is TRUE scaled n.iter default is 100.

further arguments passed to or from other methods.

. . .

bayesglm 5

#### **Details**

The program is a simple alteration of glm() that uses an approximate EM algorithm to update the betas at each step using an augmented regression to represent the prior information.

We use Student-t prior distributions for the coefficients. The prior distribution for the constant term is set so it applies to the value when all predictors are set to their mean values.

If scaled=TRUE, the scales for the prior distributions of the coefficients are determined as follows: For a predictor with only one value, we just use prior.scale. For a predictor with two values, we use prior.scale/range(x). For a predictor with more than two values, we use prior.scale/(2\*sd(x)).

We include all the glm() arguments but we haven't tested that all the options (e.g., offests, contrasts, deviance for the null model) all work.

The new arguments here are: prior.mean, prior.scale, prior.scale.for.intercept, prior.df, and scaled.

#### Value

See glm for details.

bayespolr

Bayesian Ordered Logistic or Probit Regression

# Description

Bayesian functions for ordered logistic or probit modeling with independent normal, t, or Cauchy prior distribution for the coefficients.

#### Usage

```
bayespolr(formula, data, weights, start, ...,
    subset, na.action, contrasts = NULL,
    Hess = TRUE, model = TRUE,
    method = c("logistic", "probit", "cloglog", "cauchit"),
```

bayespolr 7

```
prior.mean = 0, prior.scale = 2.5, prior.df = 1,
scaled = TRUE, prior.mean.for.cutpoints = 0,
prior.scale.for.cutpoints = 10, prior.df.for.cutpoints = 1,
n.iter = 100)
```

## **Arguments**

prior.scale.for.cutpoints

this vector.

a formula expression as for regression models, of the form 'response predicformula tors'. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. A proportional odds model will be fitted. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of 'formula' for other details. data an optional data frame in which to interpret the variables occurring in 'formula'. weights optional case weights in fitting. Default to 1. start initial values for the parameters. This is in the format 'c(coefficients, zeta)' additional arguments to be passed to 'optim', most often a 'control' argument. . . . expression saying which subset of the rows of the data should be used in the fit. subset All observations are included by default. a function to filter missing data. na.action a list of contrasts to be used for some or all of the factors appearing as variables contrasts in the model formula. logical for whether the Hessian (the observed information matrix) should be Hess returned. logical for whether the model matrix should be returned. model method logistic or probit or complementary log-log or cauchit (corresponding to a Cauchy latent variable and only available in  $R \ge 2.1.0$ ). prior.mean prior mean for the coefficients: default is 0. Can be a vector of length equal to the number of predictors (not counting the intercepts). If it is a scalar, it is expanded to the length of this vector. prior scale for the coefficients: default is 2.5. Can be a vector of length equal prior.scale to the number of predictors (not counting the intercepts). If it is a scalar, it is expanded to the length of this vector. prior.df for t distribution: default is 1 (Cauchy). Set to Inf to get normal prior distributions. Can be a vector of length equal to the number of predictors (not counting the intercepts). If it is a scalar, it is expanded to the length of this vector. if scaled = TRUE, then the prior distribution is rescaled. Can be a vector of scaled length equal to the number of cutpoints (intercepts). If it is a scalar, it is expanded to the length of this vector. prior.mean.for.cutpoints prior mean for cutpoints: default is 0. Can be a vector of length equal to the number of cutpoints (intercepts). If it is a scalar, it is expanded to the length of this vector.

prior scale for cutpoints: default is 10. Can be a vector of length equal to the number of cutpoints (intercepts). If it is a scalar, it is expanded to the length of

8 bayespolr

```
prior.df.for.cutpoints
```

for t distribution: default is 1 (Cauchy). Can be a vector of length equal to the number of cutpoints (intercepts). If it is a scalar, it is expanded to the length of this vector.

n.iter default is 100.

#### **Details**

The program is a simple alteration of polr() that augments the loglikelihood with the log of the t prior distributions for the coefficients.

We use Student-t prior distributions for the coefficients. The prior distributions for the intercepts (the cutpoints) are set so they apply to the value when all predictors are set to their mean values.

If scaled=TRUE, the scales for the prior distributions of the coefficients are determined as follows: For a predictor with only one value, we just use prior.scale. For a predictor with two values, we use prior.scale/range(x). For a predictor with more than two values, we use prior.scale/(2\*sd(x)).

#### Value

See polr for details.

binned.plot 9

|--|--|--|

## **Description**

A function that plots averages of y versus averages of x and can be useful to plot residuals for logistic regression.

## Usage

```
binned.plot(x ,y, nclass=floor(sqrt(length(x))),
    xlab="Expected Values", ylab="Average residual",
    main="Binned residual plot",
    cex.pts=0.8, col.pts=1, col.int="gray")
```

#### **Arguments**

Х	The expected values from the logistic regression.
У	The residuals values from logistic regression (observed values minus expected values).
nclass	Number of categories (bins) based on their fitted values in which the data are divided, default is $floor(sqrt(length(x)))$ .
xlab	a label for the x axis, default is "Expected Values".
ylab	a label for the y axis, default is "Average residual".
main	a main title for the plot, default is "Binned residual plot". See also title.
cex.pts	The size of points, default=0.8.
col.pts	color of points, default is black
col.int	color of intervals, default is gray

## **Details**

In logistic regression, as with linear regression, the residuals can be defined as observed minus expected values. The data are discrete and so are the residuals. As a result, plots of raw residuals from logistic regression are generally not useful. The binned residuals plot instead, after dividing the data into categories (bins) based on their fitted values, plots the average residual versus the average fitted value for each bin.

#### Value

A plot in which the gray lines indicate  $\pm 2$  standard-error bounds, within which one would expect about 95% of the binned residuals to fall, if the model were actually true.

#### Note

There is typically some arbitrariness in choosing the number of bins: each bin should contain enough points so that the averaged residuals are not too noisy, but it helps to have also many bins so as to see more local patterns in the residuals (see Gelman and Hill, Data Analysis Using Regression and Multilevel/Hierarchical Models, pag 97).

## **Examples**

coefplot

Generic Function for Making Coefficient Plot

## **Description**

Functions that plot the coefficients from a lm, glm, bugs, and polr fits.

# Usage

coefplot 11

## **Arguments**

object	fitted objects-lm, glm, bugs and polr.
	further arguments passed to or from other methods.
longnames	long variable names (vector). If not provided, use default variable names.
xlim	the x limits $(x1, x2)$ of the plot. Note that $x1 > x2$ is allowed and leads to a "reversed axis".
ylim	the y limits of the plot
xlab	a label for the x axis, default is "".
ylab	a label for the y axis, default is "".
main	a main title for the plot, default is "". See also title.
intercept	If TRUE will plot intercept, default=FALSE to get better presentation.
varnames	If FALSE will not plot variable names, default=TRUE.
cex.var	The fontsize of the varible names, default=0.8.
cex.pts	The size of data points, default=0.9.
col.pts	color of points and segments, default is black

#### **Details**

This function plots coefficients from lm, glm and polr with 1 sd and 2 sd interval bars.

## Value

Plot of the coefficients from a lm or glm fit. You can add the intercept, the variable names and the display the result of the fitted model.

corrplot

Function for Making Correlation Plot

#### **Description**

Function for making a correlation plot starting from a data matrix

## Usage

## **Arguments**

data	a data matrix
var.names	variable names of the data matrix, if not provided use default variable names
details	show more than one digits correlaton values. Default is true. FALSE is suggested to get readable output.
n.col.legend	number of legend for the color thermometer
cex.col	font size of the color thermometer
cex.var	font size of the variable names
digits	number of digits shown in the text of the color theromoeter
color	color of the plot, default is FALSE, which uses gray scale
abs	if TRUE, transform all correlation values into positive values.
•••	other plot options may be passed to this function, see $plot.default$ and $par$ .

#### **Details**

The function adapts the R function for Figure 8 in Tian Zheng, Matthew Salganik, and Andrew Gelman, 2006, "How many people do you know in prison?: using overdispersion in count data to estimate social structure in networks", Journal of the American Statistical Association, Vol.101, No. 474: p.409-23.

#### Value

A correlation plot.

display

Functions for Processing lm, glm, mer and polr Output

## **Description**

This generic function gives a clean printout of lm, glm, mer and polr objects.

display 15

#### **Usage**

```
display (object, ...)
# methods for display()
    display.lm (object, digits=2)
    display.glm (object, digits=2)
    display.mer (object, digits=2)
    display.polr (object, digits=2)
```

## **Arguments**

object	The output of a call to lm, glm, mer, polr, or related regressions function with n data points and k predictors.
	further arguments passed to or from other methods.
digits	number of significant digits to display.

#### **Details**

This generic function gives a clean printout of lm, glm, mer and polr objects, focusing on the most pertinent pieces of information: the coefficients and their standard errors, the sample size, number of predictors, residual standard deviation, and R-squared. Note: R-squared is automatically displayed to 2 digits, and deviances are automatically displayed to 1 digit, no matter what.

#### Value

Coefficients and their standard errors, the sample size, number of predictors, residual standard deviation, and R-squared

# Note

Output are the model, the regression coefficients and standard errors, and the residual sd and R-squared (for a linear model), or the null deviance and residual deviance (for a generalized linear model).

go

Function to Recall Last Source File

# **Description**

A function that like source() but recalls the last source file names by default.

# Usage

```
go(..., add=FALSE, timer=FALSE)
```

#### **Arguments**

add list of filenames as character strings.

add these names to the current list? if replace, then FALSE.

timer time the execution time of go().

## Author(s)

Jouni Kerman (jouni@kerman.com) (kerman@stat.columbia.edu)

```
go('myprog')  # will run source('myprog.r')
go()  # will run source('myprog.r') again
go('somelib',add=TRUE)  # will run source('myprog.r') and source('somelib.r')
go('myprog','somelib')  # same as above
go('mytest')  # will run source('mytest') only
go()  # runs source('mytest') again
G  # short cut to call go()
```

18 invlogit

invlogit

Logistic function

# Description

Inverse-logit function, transforms continuous values to the range (0, 1)

## Usage

```
invlogit(x)
```

# **Arguments**

Х

A vector of continuous values

#### **Details**

The Inverse-logit function defined as:  $logit^-1(x) = e^x/(1+e^x)$  transforms continuous values to the range (0, 1), which is necessary, since probabilities must be between 0 and 1 and maps from the linear predictor to the probabilities

## Value

A vector of estimated probabilities

# Author(s)

Andrew Gelman (gelman@stat.columbia.edu), M.Grazia Pittau (grazia@stat.columbia.edu)

## References

Inv.logit <- invlogit(b0+b1*x1+b2*x2)
plot(b0+b1*x1+b2*x2, Inv.logit)</pre>
```

lalonde 19

lalonde

Lalonde Dataset

## **Description**

Dataset used by Dehejia and Wahba (1999) to evaluate propensity score matching.

## Usage

```
data(lalonde)
```

#### **Format**

A data frame with 445 observations on the following 12 variables.

age age in years.

educ years of schooling.

black indicator variable for blacks.

hisp indicator variable for Hispanics.

married indicator variable for martial status.

nodegr indicator variable for high school diploma.

re74 real earnings in 1974.

re75 real earnings in 1975.

re78 real earnings in 1978.

**u74** indicator variable for earnings in 1974 being zero.

**u75** indicator variable for earnings in 1975 being zero.

treat an indicator variable for treatment status.

## **Details**

Two demos are provided which use this dataset. The first, DehejiaWahba, replicates one of the models from Dehejia and Wahba (1999). The second demo, AbadieImbens, replicates the models produced by Abadie and Imbens http://elsa.berkeley.edu/~imbens/matlab/lalonde\_exper\_04feb2.m. Many of these models are found to produce good balance for the Lalonde data.

# Note

This documentation is adapted from Matching package.

matching

Matching

# Description

Function for processing matching with propensity score

# Usage

```
matching(z, score)
```

# Arguments

z vector of indicators for treatment or control.

score vector of the propensity scores in the same order as z.

## **Details**

Function for matching each treatment unit in turn the control unit (not previously chosen) with the closest propensity score

## Value

The function returns a vector of indices that the corresponding unit is matched to. 0 means matched to nothing.

mcsamp 21

## **Examples**

mcsamp

Quick Function to Run mcmcsamp() in lme4

# Description

The function for MCMC sampling for lmer and glmer objects and convert to Bugs objects for easy display

#### Usage

#### **Arguments**

object	lmer or glmer objects
n.chains	number of MCMC chains
n.iter	number of iteration for each MCMC chain
n.burnin	number of burnin for each MCMC chain
n.thin	number of thin for each MCMC chain
saveb	if 'TRUE', causes the values of the random effects in each sample to be saved.
make.bugs.object	
	C .1

tranform the output into bugs object, default is TRUE

## **Details**

This generic generates a sample from the posterior distribution of the parameters of a fitted model using Markov Chain Monte Carlo methods.

#### Value

An object of (S3) class "mcmc" suitable for use with the functions in the "coda" package.

#### Author(s)

Andrew Gelman (gelman@stat.columbia.edu); Yu-Sung Su (ys463@columbia.edu)

rescale

Function for Standardizing by Centering and Dividing by 2 sd's

# Description

This function standardizes a variable by centering and dividing by 2 sd's with exceptions for binary variables.

## Usage

```
rescale(x, binary.inputs)
```

# **Arguments**

```
{\tt x} a vector binary.inputs options for standardizing binary variables
```

## Value

the standardized vector

## Author(s)

se.coef

Extract Standard Errors of Model Coefficients

## Description

These functions extract standard errors of model coefficients from objects returned by modeling functions.

# Usage

```
se.coef (object)
se.fixef (object)
se.ranef (object)

# methods for se.coef()
se.coef.lm (object)
se.coef.glm (object)
se.coef.mer (object)
```

## **Arguments**

object of lm, glm, lmer and glmer fit

## Details

se.coef extracts standard errors from objects returned by modeling functions. se.fixef extracts standard errors of the fixed effects from objects returned by lmer and glmer functions. se.ranef extracts standard errors of the random effects from objects returned by lmer and glmer functions.

## Value

se.coef gives lists of standard errors for coef, se.fixef gives a vector of standard errors for fixef and se.ranef gives a list of standard errors for ranef.

```

sim

Functions to Get Posterios Distributions

# Description

This generic function gets posterior simulations of sigma and beta from a lm object, or simulations of beta from a glm object, or simulations of beta from a mer object

sim 27

## Usage

```
sim(object, ...)
# methods for sim()
sim.lm (object, n.sims = 100)
sim.glm (object, n.sims = 100)
sim.mer (object, n.sims = 100)
```

## **Arguments**

object the output of a call to "lm" with n data points and k predictors.
... further arguments passed to or from other methods.
n.sims number of independent simulation draws to create.

#### Value

vector of n.sims random draws of sigma (for glm's, this just returns a vector of 1's or else of the square root of the overdispersion parameter if that is in the model)

beta.sim matrix (dimensions n.sims x k) of n.sims random draws of beta

#### Author(s)

```

standardize

Function for Standardizing Regression Predictors by Centering and Dividing by 2 sd's

## **Description**

Numeric variables that take on more than two values are each rescaled to have a mean of 0 and a sd of 0.5; Binary variables are rescaled to have a mean of 0 and a difference of 1 between their two categories; Non-numeric variables that take on more than two values are unchanged; Variables that take on only one value are unchanged

# Usage

```
standardize(object, unchanged = NULL,
    standardize.y = FALSE, binary.inputs = "center")
```

## Arguments

```
object an object of class "lm" or "glm"
unchanged vector of names of parameters to leave unstandardized
```

standardize 29

```
standardize.y
if TRUE, the outcome variable is standardized also
binary.inputs
options for standardizing binary variables
```

#### **Details**

"0/1" (rescale so that the lower value is 0 and the upper is 1) "-0.5/0.5" (rescale so that the lower value is -0.5 and upper is 0.5) "center" (rescale so that the mean of the data is 0 and the difference between the two categories is 1) "full" (rescale by subtracting the mean and dividing by 2 sd's) "leave.alone" (do nothing)
